INTRODUCTION

AI can now create human faces that look completely real, often used in fake profiles and scams. Most detectors fail once social media compresses and resizes the image. Our project builds a model that stays accurate under these conditions.

METHODOLOGY

We adapt Xception, a deep CNN pre-trained model on millions of images, to classify faces as Real or Fake. Training images are randomly compressed, rotated, and noised to simulate social-media processing.

EXPERIMENTS

The model was trained on a balanced dataset of real and AI-generated human face images collected from multiple sources. The model achieved high detection accuracy on the test set, showing strong ability to classify both real and fake faces.

CONCLUSION

AI models can help detect fake human face images and reduce the spread of manipulated content on social media. Our model achieved strong accuracy in classifying real and AI-generated faces. However, using this type of model directly on social media platforms is still a challenge because we cannot easily access or use real platform data due to privacy, security, and data availability limitations.
